There is abundant evidence that student achievement is related to home background factors, and to students' activities and attitudes. To help interpret the achievement results, Chapter 4 provides detailed information about students' home backgrounds, how they spend their time out of school, their self-concept in science, and their attitudes towards science.

and Attitudes Towards Science

Students' Backgrounds

APTER

parent finished university. Students at the low level had 25 or fewer books in the home, not all three study aids, and parents that had not completed secondary education. The remaining students were assigned to the medium level.

The first page of the display also presents the percentage of students at each level of the index for each Benchmarking participant and for selected reference countries, together with the average science achievement for those students. Standard errors are also shown. Entities are ordered by the percentage of students at the high index level. The international average across all TIMSS 1999 countries is shown at the bottom. The second page of the display graphically shows the percentage of students at the high index level for each entity. There was a substantial difference in the average science achievement of students at the index levels in every entity for which data were available. This is reflected in the international average for the TIMSS 1999 countries, where the achievement difference between students at the high level (558) and the low level (431) amounted to 127 score points.

Relative to other countries, the United States had a large percentage of students at the high level of the home educational resources index (22 percent). Of the TIMSS 1999 countries included in Exhibit 4.1, only Canada had a comparable percentage of students at the high level (27 percent). The relatively high standing of the United States on this index was reflected in the results for the Benchmarking jurisdictions, most of which had larger percentages of students in the high category of home educational resources than did most of the comparison countries.

The Benchmarking participants with the greatest percentages of students at the high level included the Naperville School District (56 percent), the First in the World Consortium (45 percent), the Academy School District (44 percent), and Montgomery County (39 percent). With the exception of Montgomery County, these were also among the top-performing jurisdictions in science. The four urban Benchmarking school districts that at work. For example, Chinese Taipei had about the same percentage of students (eight percent) at the high index level as Rochester, Chicago, Jersey City, and Miami-Dade, but the average science achievement of its students at that level was considerably higher. In fact, the international average for all 38 TIMSS 1999 countries was just nine percent. There is also evidence that financial resources alone will not result in high academic achievement. According to OECD analyses for 1994, U.S. schools ranked third highest among 22 countries in perstudent expenditures on primary schools and third highest among 23 countries on secondary schools.³

Exhibits R1.1 through R1.3 in the reference section present more detailed information on the student responses that were combined in the home educational resources index. Exhibit R1.1 shows the percentage of eighth-grade students in each of the Benchmarking jurisdictions and comparison countries who had a dictionary, study desk or table, or computer, and shows that students reporting having all three had higher average science achievement than those without all three.

Exhibit R1.2 shows for each entity the percentage of students at each of five ranges of numbers of books in the home in relation to average science achievement. In most jurisdictions, the more books students reported in the home, the higher their science achievement.

The percentages of students in each of five categories of parents' educational level are shown in Exhibit R1.3, together with their average science achievement. Although countries did their best to use educational categories that were comparable across all countries, the range of educational provision made this difficult. About half of the participating countries had to modify the response options presented to students in the questionnaire in order to conform to their national education system. Exhibit R1.4 provides details of how these modifications were aligned with the categories of parents' education used in this report. Despite the different educational approaches, structures, and organizations across the TIMSS 1999 countries, it is clear that parents' education is positively related to students' science achievement. The pattern across countries was that eighth-grade students whose parents had more education were also those who had higher achievement in science. The same was true for nearly all Benchmarking jurisdictions.

As information technology and the Internet become more and more important as an educational resource, those who do not have access to this technology will be increasingly at a disadvantage. To provide information about this "digital divide," Exhibit 4.2 presents the percentage of students in each entity that reported having a computer at home,

³ Education at a Glance: OECD Indicators (1997), Paris, France: Organization for Economic Cooperation and Development. The OECD adjusted the expenditure estimates for the purchasing power of each country's currency.

Index of Home Educational Resources

Index based on studen responses to three que about home education resources: number of b in the home; educationa in the home (computer, desk/table for own use dictionary); parents' education (see referen exhibits R1.1-R1.3). High indicates more than 10 books in the home; all educational aids; and e parent's highest level o education is finished university. Low level ind 25 or fewer books in tl home; not all three educational aids; and b parents' highest level o education is some seco or less or is not known Medium level includes other possible combination of responses. See refer exhibit R1.4 for nation definitions of educatio levels; response catego were defined by each co to conform to their ow educational system and not be strictly compara across countries.

States in *italics* did not fully satisfy guidelines for sample participation rates (see Appendix A for details).

 Standard errors appear in parentheses. Because results are rounded to the nearest whole number, some totals may appear inconsistent. A dash (--) indicates data are not available. A tilde (~-) indicates insufficient data to report achievement.

together with their average science achievement. Compared with some of the reference countries as well as the international average (45 percent), students in the Benchmarking jurisdictions reported relatively high levels of computer ownership; more than 70 percent of students in each state reported having a computer at home. In the wealthier districts and consortia such as the Academy School District, the First in the World Consortium, Montgomery County, and the Naperville School District, nore than 90 percent of students so reported. Even in the less advanaged public school districts, more than half the students reported having a computer at home. In almost every entity, students with a computer at home had higher average science achievement than those without.

Students who speak a language (or languages) in the home that is different from the language spoken in school sometimes benefit from being multilingual. However, when they are still developing proficiency in the language of instruction they can be at a disadvantage in learning situations. Exhibit 4.3 contains students' reports of how frequently they speak the language of the TIMSS test at home in relation to their average science achievement. Students from homes where the language of the test is the or almost always spoken had higher average achievement than

i loss frequently. In all of the Benchmarking states

home. The percentage of students speak. home was lower in a number of school districts, no public school systems in Chicago, Jersey City, and M

Txhibit 4.4 presents students' reports of thed States as a whole, 63 percent repTrck, 12 percent Hispanic, forPerican Indian orPerican Indian orPerican Indian or

Southwest Pennsylvania Math and Science Collaborative, with more than 80 percent white students. Ethnically more diverse jurisdictions included Chicago (47 percent black, 37 percent Hispanic), Jersey City (35 percent black, 35 percent Hispanic, 16 percent Asian/Pacific Islander), Miami-Dade (31 percent black, 55 percent Hispanic), Montgomery County (16 percent black, 12 percent Hispanic, 15 percent Asian/Pacific Islander), and Rochester (56 percent black, 16 percent Hispanic).

By the end of the eighth grade, students in most countries can say what their expectations are for further education. Although one-quarter or more of the students in some countries did not know, Exhibit 4.5 shows that, on average across countries, more than half the students reported that they expected to finish university (a four-year degree program or equivalent). The United States was among the countries that had the highest percentage, with almost 80 percent expecting to finish university. In almost every country, also, there was a positive association between educational expectations and science achievement. Among Benchmarking participants, the percentage of students expecting to finish university was also high, even in areas with low student achievement, as more than 70 percent of students in all Benchmarking entities reported that they expected to finish university.

Exhibits R1.5 to R1.7 in the reference section present eighth-grade students' reports about how they, their mothers, and their friends feel about the importance of doing well in various academic and nonacademic activities. On average across the TIMSS 1999 countries, more than 90 percent of students reported that they and their mothers agreed that it was important to do well in science, mathematics, and language. Somewhat fewer reported that their friends agreed (77 to 86 percent). As might be anticipated, slightly more students reported that they and their friends felt it was important to have fun (92 percent) than reported that their mothers found this important (85 percent). More moderate agreement was reported for the importance of doing well in sports (from 81 to 87 percent). In general, the reports of students in the Benchmarking jurisdictions resembled those in the United States overall. It is noteworthy, however, that students in the U.S. and in many Benchmarking jurisdictions were less likely than their counterparts internationally, on average, to report that their friends think it is important to do well in science, mathematics, and language, and were more likely to report that they, their mothers, and their friends think it is important to have fun.

Students were also asked why they needed to do well in science (see Exhibit R1.8). In most entities, getting into their desired secondary school or university was a stronger motivating factor than was pleasing their parents or getting their desired job.

Background data provided by students.

States in *italics* did not fully satisfy guidelines for sample participation rates (see Appendix A for details).

() Standard errors appear in parentheses. Because results are rounded to the nearest whole number, some totals may appear inconsistent.

A tilde (~) indicates insufficient data to report achievement.

An "r" indicates a 70-84% student response rate.

Background data provided by students.

- * Response categories were defined by each country to conform to their own educational system and may not be strictly comparable across countries. See Reference Exhibit R1.4 for country definitions of educational levels.
- ³ In most countries, finish secondary school corresponds to completion of an upper-secondary track terminating after 11 to 13 years of schooling (ISCED level 3 vocational, apprenticeship or academic tracks).
- 1 In most countries, finish university is defined as completion of at least a 4-year degree program at a university or an equivalent institute of higher education. For the United States, includes community college, college, or university.
- ² In some countries, may include higher post-secondary education levels.
- States in *italics* did not fully satisfy guidelines for sample participation rates (see Appendix A for details). () Standard errors appear in parentheses. Because results are rounded to the nearest whole number, some totals may appear inconsistent.

A dash (--) indicates data are not available. A tilde (~-) indicates insufficient data to report achievement.

with higher achievement. In many of the Benchmarking entities, students at the medium level of the study index had average achievement that was as high as or higher than that of students at the high level. This pattern suggests that, compared with their higher-achieving counterparts, the lower-performing students may do less homework, either because they simply do not do it or because their teachers do not assign it, or more homework, perhaps in an effort to keep up academically.

More detailed information on the amount of time students reported spending on science homework is presented in Exhibit 4.7. The results reveal that while students on average across all the TIMSS 1999 countries spent one hour per day doing science homework, students in the Benchmarking jurisdictions and the United States spent less. The exhibit also shows the percentages of students that reported spending one hour or more, less than one hour, and no time at all studying science or doing science homework on a normal school day, together with their average science achievement. On average across all countries, 36 percent of students reported spending one hour or more per day doing science homework. None of the Benchmarking entities reported this much homework. The highest levels of science homework were reported in

more time on these activities and on sports, and less time reading for enjoyment. For example, in the four jurisdictions with the lowest average science achievement – the public school systems of Rochester, Chicago, Jersey City, and Miami-Dade – students reported watching television or videos for about three to three and one-half hours (as well as playing computer games for about one hour).

Background data provided by students.

Average hours based on: No time=0; less than 1 hour=.5; 1-2 hours=1.5; 3-5 hours=4; more than 5 hours=7.

States in *italics* did not fully satisfy guidelines for sample participation rates (see Appendix A for details).

() Standard errors appear in parentheses. Because results are rounded to the nearest whole number, some totals may appear inconsistent.

A dash (--) indicates data are not available.

How Do Students Perceive Their Ability in the Sciences?

To investigate how students think of their abilities in science, TIMSS created an index of students' self-concept in the sciences (scs). It is based on student's responses to four statements about their science ability:

- I would like science much more if it were not so difficult
- Although I do my best, science is more difficult for me than for many of my classmates
- Nobody can be good in every subject, and I am just not talented in science
- Science is not one of my strengths.

In countries where the sciences are taught as separate subjects, students were asked about each subject separately.

Students who disagreed or strongly disagreed with all four statements were assigned to the high level of the index, while students who agreed or strongly agreed with all four were assigned to the low level. The medium level includes all other combinations of responses. (As an example of one of the components of the index, Exhibit R1.11 in the reference section shows the percentages of agreement for the statement "science is not one of my strengths.")

The percentages of eighth-grade students at each index level, and their average science achievement, are presented in Exhibit 4.8. This fourpage display summarizes the data in one panel for the countries that teach science as a single subject (including all the Benchmarking participants), and in separate panels for earth science, biology, physics, and chemistry for countries that teach the sciences separately. Among all the single-science countries, the United States had the greatest percentage of students at the high level of the self-concept index: 45 percent compared with 26 percent on average across all countries. Several of the Benchmarking participants had even greater percentages at the high level, notably the First in the World Consortium and North Carolina, with more than 50 percent of students at this level.

Although there was a clear positive association between self-concept and science achievement within every country and within every Benchmarking jurisdiction, the relationship across entities was more complex. Several countries with high average science achievement, including Singapore, Japan, Hong Kong, Chinese Taipei, and Korea, had relatively low percentages of students (21 percent or less) in the high selfconcept category. Since all of these are Asian Pacific countries, they may share cultural traditions that encourage a modest self-concept.

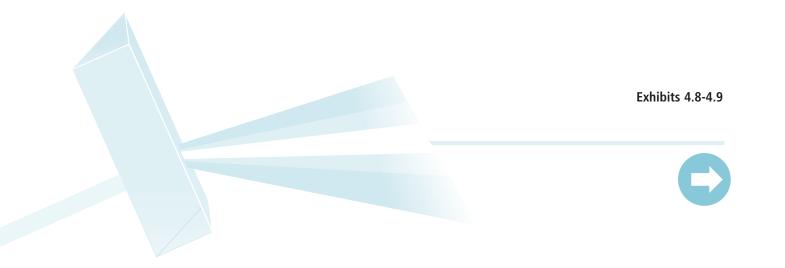

In countries teaching the sciences as separate subjects, the percentage of students at the high level of the science self-concept index was greatest for biology and earth science, with more than 40 percent of students in the high category on average. The percentage was lower for physics (32 percent on average) and chemistry (28 percent). Generally, countries with high percentages of students in the high category for one subject had high percentages in the other subjects also. The largest percentages of students in the high category were in the Russian Federation and the Netherlands⁴ in all subjects. The positive association between science self-concept and science achievement that was found for science as a single subject was also evident in each of the science subject areas.

Results of analyses of the TIMSS 1995 data by gender⁵ reveal not only that boys outperformed girls in science at the eighth grade in many countries, but that they attached more importance to doing well in science and mathematics than in language, and to doing well in science in order to get a good job. Not surprisingly, therefore, many countries, including the United States, showed differences in science self-concept between girls and boys. Exhibit 4.9 presents the percentages of girls and boys in the Benchmarking entities and in the reference countries at the high, medium, and low levels of the science self-concept index. Despite the gender differences in the United States as a whole, there were few significant differences among Benchmarking participants. There were greater percentages of boys at the high index level in Massachusetts, Missouri, Naperville, and the Southwest Pennsylvania Math and Science Collaborative. Naperville had a greater percentage of girls at the low level. Greater percentages of girls at the medium level were found in Massachusetts, Oregon, and Rochester.

⁵ Mullis, I.V.S., Martin, M.O., Fierros, E.G., Goldberg, A.L., and Stemler, S.E. (2000), *Gender Differences in Achievement: IEA's Third International Mathematics and Science Study*, Chestnut Hill, MA: Boston College.

⁴ Physics and chemistry are taught as one subject in the Netherlands. Student responses are reported in the physics panel of Exhibit 4.8.

Index of Students' Self-Concept in the Sciences

Index based on students' responses to four statements about their science ability: 1) I would like science much more if it were not so difficult; 2) although I do my best, science is more difficult for me than for many of my classmates; 3) nobody can be good in every subject, and I am just not talented in science; 4) science is not one of my strengths. In countries where science is taught as separate subjects, students were asked about each subject area separately. High level indicates student disagrees or strongly disagrees with all four statements. Low level indicates student agrees or strongly agrees with all four statements. Medium level includes all other possible combinations of responses.

What Are Students' Attitudes Towards the Sciences?

Generating positive attitudes towards science among students is an important goal of science education in many jurisdictions. To gain some understanding of eighth-graders' views about the utility of science and their enjoyment of it as a school subject, TIMSS created an index of positive attitudes towards the sciences (PATS). Students were asked to state their agreement with the following five statements:

- I like science
- I enjoy learning science
- Science is boring⁶
- Science is important to everyone's life
- I would like a job that involved using science.

In countries where the sciences are taught as separate subjects students were asked about each subject area separately.

For each statement, students responded on a four-point scale indicating whether their feelings about science were strongly positive, positive, negative, or strongly negative. The responses were averaged, with students being placed in the high category if their average indicated a positive or strongly positive attitude. Students with a negative or strongly negative attitude on average were placed in the low category. The students between these extremes were placed in the medium category. The results are presented in Exhibit 4.10 in a four-page display, in a single panel for the countries that teach science as a single subject (this panel includes the Benchmarking participants) and in separate panels for earth science, biology, physics, and chemistry for countries that teach the sciences separately. (Additional information on students' liking science, one of the components of the index, is provided in Exhibit R1.12 in the reference section.)

In countries where science is taught as a single subject, students generally had positive attitudes towards the sciences, with 40 percent on average across all TIMSS 1999 countries in the high category and a further 49 percent in the medium category. Only 10 percent of students were in the low category. Percentages for the United States did not vary much from the international averages. Benchmarking jurisdictions with large percentages of students at the high level included the Rochester City School District and North Carolina (40 percent). Jurisdictions with somewhat less favorable attitudes included Idaho, the Delaware Science Coalition,

⁶ The response categories for this statement were reversed in constructing the index.

Chapter

Massachusetts, the Fremont/Lincoln/Westside Public Schools, Pennsylvania, Oregon, and the Chicago Public Schools, where less than 30 percent of the students were at the high level. The comparison countries with the least positive attitudes were Chinese Taipei, Hong Kong, Japan, and Korea. Since these are all countries with high average science achievement, it may be that the students follow a demanding science curriculum that leads to high achievement but little enthusiasm for the subject matter. However, there was a clear positive association between attitudes towards the sciences and science achievement on average across all the TIMSS 1999 countries and in many of the Benchmarking entities.

Attitudes towards the science subject areas were somewhat less positive among the separate-science countries. The most positive were towards biology (32 percent in the high category, on average) and earth science (27 percent), and the least positive towards physics and chemistry (19 and 23 percent, respectively). Among the four separate-science comparison countries, the Russian Federation and the Czech Republic had the greatest percentage of students at the high level in all of the subject areas. The relationship between positive attitudes and science achievement was not as clear for the separate-science subject areas as it was for science as a single subject. In physics and chemistry, students at the high level of the index had substantially higher average achievement than students at the medium and low levels on average across all the TIMSS 1999 countries, but this was not the case for earth science and biology.

Exhibit 4.11 shows the percentages of girls and boys in each of the comparison countries and Benchmarking jurisdictions at each level of the index of positive attitudes towards the sciences. Although the United States, like many of the other countries, had significantly different percentages of girls and boys at the index levels, there were few significant differences among the Benchmarking participants. North Carolina was the only state to show a difference, with a greater percentage of boys at the high level and of girls at the medium level. The Delaware Science Coalition and Naperville had greater percentages of boys at the high level. For the separate-science countries on average, there were significantly greater percentages of boys than girls at the high level of the index in earth science, physics, and chemistry, but a larger percentage of girls in biology.

Index of Students'	
Positive Attitudes	
Towards the Sciences	5

Index based on students' responses to five statements about science: 1) I like science; 2) I enjoy learning science; 3) science is boring (reversed scale); 4) science is important to everyone's life; 5) I would like a job that involved using science. Average is computed across the five items based on a 4-point scale: 1 = strongly negative; 2 = negative; 3 = positive; 4 = strongly positive. In countries where science is taught as separate subjects, students were asked about each subject area separately. High level indicates average is greater than 3. Medium level indicates average is greater than 2 and less than or equal to 3. Low level indicates average is less than or equal to 2.

▲ Significantly higher than other gender

Significance tests adjusted for multiple comparisons

Background data provided by students.

144

- * Countries administered either a general/integrated science or separate subject area form of the questionnaire. In countries that administered the separate subject area form, students were asked about each subject area separately.
- ^a Chinese Taipei: Students were asked about 'natural science'; data pertain to grade 8 physics/chemistry course.

b Netherlands: Data in physics panel pertain to physics/chemistry course.

States in *italics* did not fully satisfy guidelines for sample participation rates (see Appendix A for details). () Standard errors appear in parentheses. Because results are rounded to the nearest whole number,

some totals may appear inconsistent. A dash (–) indicates data are not available.

An "s" indicates a 50-69% student response rate.
